Algorithms

Chapter 3. Asymptotic Computational Complexity

- Taken from the instructor's resource of *Discrete Mathematics* and *Its Applications*, 7/e
- Edited by Shin Hong hongshin@handong.edu

The Growth of Functions

- In both computer science and in mathematics, there are many many times when we care about how fast a function grows.
- In computer science, we want to understand how quickly an algorithm can solve a problem as the size of the input grows.
 - We can compare the efficiency of two different algorithms for solving the same problem.
 - We can also determine whether it is practical to use a particular algorithm as the input grows.
 - We'll study these questions in Section 3.3.

Big-O Notation (1/3)

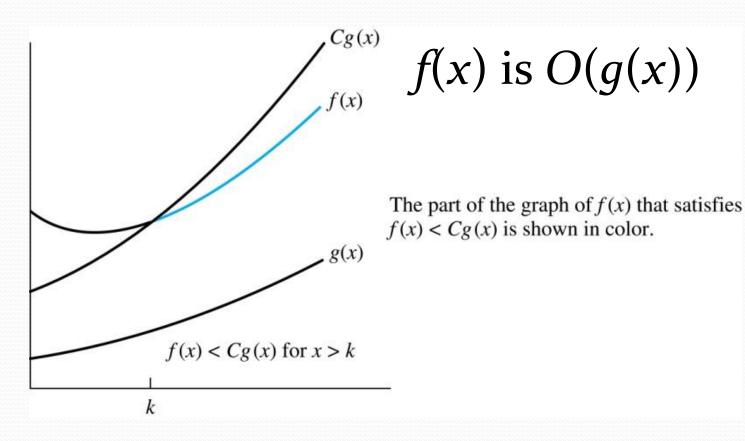

• Let f and g be functions from the set of real numbers to the set of real numbers. We say that f(x) is O(g(x)) if there are constants C and k such that

$$|f(x)| \le C|g(x)|$$

whenever x > k. (illustration on next slide)

- This is read as "f(x) is big-O of g(x)" or "g asymptotically dominates f."
- The constants C and k are called *witnesses* to the relationship f(x) is O(g(x)). Only one pair of witnesses is needed.

Big-O Notation (2/3)

Big-O Notation (3/3)

- If one pair of witnesses is found, then there are infinitely many pairs. We can always make the k or the C larger and still maintain the inequality $|f(x)| \le C|g(x)|$.
 - Any pair C' and k' where C < C' and k < k' is also a pair of witnesses since $|f(x)| \le C|g(x) \le C'|g(x)|$ whenever x > k' > k.
- You may see "f(x) = O(g(x))" instead of "f(x) is O(g(x))."
 - But this is an abuse of the equals sign since the meaning is that there is an inequality relating the values of *f* and *g*, for sufficiently large values of x.
 - It is ok to write $f(x) \in O(g(x))$, because O(g(x)) represents the the set of functions that are O(g(x)).
- Usually, we will drop the absolute value sign since we will always deal with functions that take on positive values.

Using the Definition of Big-O Notation

Example: Show that $f(x) = x^2 + 2x + 1$ is $O(x^2)$.

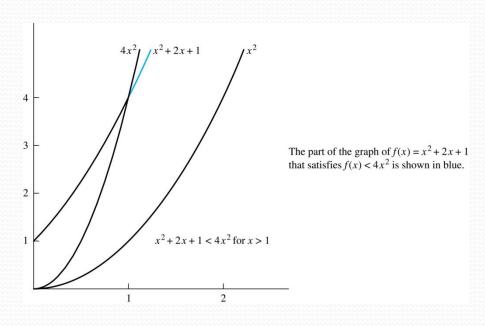

Solution: Since when x > 1, $x < x^2$ and $1 < x^2$

$$0 \le x^2 + 2x + 1 \le x^2 + 2x^2 + x^2 = 4x^2$$

- Can take C = 4 and k = 1 as witnesses to show that f(x) is $O(x^2)$ (see graph on next slide)
- Alternatively, when x > 2, we have $2x \le x^2$ and $1 < x^2$. Hence, $0 \le x^2 + 2x + 1 \le x^2 + x^2 + x^2 = 3x^2$ when x > 2.
 - Can take C = 3 and k = 2 as witnesses instead.

Illustration of Big-O Notation

$$f(x) = x^2 + 2x + 1$$
 is $O(x^2)$

Big-O Notation

- Both $f(x)=x^2+2x+1$ and $g(x)=x^2$ are such that f(x) is O(g(x)) and g(x) is O(f(x)). We say that the two functions are of the *same order*. (More on this later)
- If f(x) is O(g(x)) and h(x) is larger than g(x) for all positive real numbers, then f(x) is O(h(x)).
- Note that if $|f(x)| \le C|g(x)|$ for x > k and if |h(x)| > |g(x)| for all x, then $|f(x)| \le C|h(x)|$ if x > k. Hence, f(x) is O(h(x)).
- For many applications, the goal is to select the function g(x) in O(g(x)) as small as possible (up to multiplication by a constant, of course).

Using the Definition of Big-O Notation

Example: Show that $7x^2$ is $O(x^3)$.

Solution: When x > 7, $7x^2 < x^3$. Take C = 1 and k = 7 as witnesses to establish that $7x^2$ is $O(x^3)$.

(Would C = 7 and k = 1 work?)

Example: Show that n^2 is not O(n).

Solution: Suppose there are constants C and k for which $n^2 \le Cn$, whenever n > k. Then (by dividing both sides of $n^2 \le Cn$) by n, then $n \le C$ must hold for all n > k. A contradiction!

Big-O Estimates for Polynomials

```
Example: Let f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_o where a_0, a_1, \dots, a_n are real numbers with a_n \neq 0. Then f(x) is O(x^n).

Uses triangle inequality, an exercise in Section 1.8.

|f(x)| = |a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x^1 + a_1|
\leq |a_n| x^n + |a_{n-1}| x^{n-1} + \cdots + |a_1| x^1 + |a_1|
= x^n (|a_n| + |a_{n-1}| / x + \cdots + |a_1| / x^{n-1} + |a_1| / x^n)
\leq x^n (|a_n| + |a_{n-1}| + \cdots + |a_1| + |a_1|)
```

- Take $C = |a_n| + |a_{n-1}| + \dots + |a_1| + |a_1|$ and k = 1. Then f(x) is $O(x^n)$.
- The leading term $a_n x^n$ of a polynomial dominates its growth.

Big-Theta Notation

 Θ is the upper case version of the lower case Greek letter θ .

- **Definition**: Let f and g be functions from the set of integers or the set of real numbers to the set of real numbers. The function f(x) is $\Theta(g(x))$ if f(x) is O(g(x)) and f(x) is $\Omega(g(x))$.
- We say that "f is big-Theta of g(x)" and also that "f(x) is of order g(x)" and also that "f(x) and g(x) are of the same order."
- f(x) is $\Theta(g(x))$ if and only if there exists constants C_1 , C_2 and k such that $C_1g(x) < f(x) < C_2g(x)$ if x > k. This follows from the definitions of big-O and big-Omega.

Big Theta Notation

Example: Show that the sum of the first n positive integers is $\Theta(n^2)$.

Solution: Let $f(n) = 1 + 2 + \dots + n$.

- We have already shown that f(n) is $O(n^2)$.
- To show that f(n) is $\Omega(n^2)$, we need a positive constant C such that $f(n) > Cn^2$ for sufficiently large n. Summing only the terms greater than n/2 we obtain the inequality

$$1 + 2 + \dots + n \ge \lceil n/2 \rceil + (\lceil n/2 \rceil + 1) + \dots + n$$

$$\ge \lceil n/2 \rceil + \lceil n/2 \rceil + \dots + \lceil n/2 \rceil$$

$$= (n - \lceil n/2 \rceil + 1) \lceil n/2 \rceil$$

$$\ge (n/2)(n/2) = n^2/4$$

• Taking $C = \frac{1}{4}$, $f(n) > Cn^2$ for all positive integers n. Hence, f(n) is $\Omega(n^2)$, and we can conclude that f(n) is $\Theta(n^2)$.

Big-Theta Notation

Example: Show that $f(x) = 3x^2 + 8x \log x$ is $\Theta(x^2)$. **Solution**:

- $3x^2 + 8x \log x \le 11x^2$ for x > 1, since $0 \le 8x \log x \le 8x^2$.
 - Hence, $3x^2 + 8x \log x$ is $O(x^2)$.
- x^2 is clearly $O(3x^2 + 8x \log x)$
- Hence, $3x^2 + 8x \log x$ is $\Theta(x^2)$.

The Complexity of Algorithms (1/2)

- Given an algorithm, how efficient is this algorithm for solving a problem given input of a particular size?
 - Time complexity How much time does this algorithm use to solve a problem?
 - Space complexity How much computer memory does this algorithm use to solve a problem?
- To analyze the time complexity of algorithms, we determine the number of operations, such as comparisons and arithmetic operations (addition, multiplication, etc.)
- We will focus on the worst-case time complexity of an algorithm. This provides an upper bound on the number of operations an algorithm uses to solve a problem with input of a particular size.

The Complexity of Algorithms (2/2)

- We will measure time complexity in terms of the number of operations an algorithm uses and we will use big-O and big-Theta notation to estimate the time complexity.
- We can use this analysis to see whether it is practical to use this
 algorithm to solve problems with input of a particular size. We can also
 compare the efficiency of different algorithms for solving the same
 problem.
- We ignore implementation details (including the data structures used and both the hardware and software platforms) because it is extremely complicated to consider them.

Complexity Analysis of Algorithms

Example: Describe the time complexity of the algorithm for finding the maximum element in a finite sequence.

```
procedure max(a_1, a_2, ...., a_n: integers)
max := a_1
for i := 2 to n
  if max < a_i then max := a_i
return max \ \{max \text{ is the largest element}\}
```

Solution: Count the number of comparisons.

- The $max < a_i$ comparison is made n-2 times.
- Each time *i* is incremented, a test is made to see if $i \le n$.
- One last comparison determines that i > n.
- Exactly 2(n-1) + 1 = 2n 1 comparisons are made.

Hence, the time complexity of the algorithm is $\Theta(n)$.

Worst-Case Complexity of Linear Search

Ex. Determine the time complexity of the linear search algorithm.

```
procedure linear search(x: integer, a_1, a_2, ..., a_n: distinct integers)
i := 1
while (i \le n \text{ and } x \ne a_i)
i := i + 1
if i \le n \text{ then } location := i
else location
```

Solution: Count the number of comparisons.

- At each step two comparisons are made; $i \le n$ and $x \ne a_i$.
- To end the loop, one comparison $i \le n$ is made.
- After the loop, one more $i \le n$ comparison is made.

If $x = a_i$, 2i + 1 comparisons are used. If x is not on the list, 2n + 1 comparisons are made and then an additional comparison is used to exit the loop. So, in the worst case 2n + 2 comparisons are made. Hence, the complexity is $\Theta(n)$.
